Investigation of Single-Input Multiple-Output Wireless Power Transfer Systems Based on Optimization of Receiver Loads for Maximum Efficiencies

Sejin Kim · Sungyoun Hwang · Sanghoek Kim · Bomson Lee*

Abstract

In this paper, the efficiency of single-input multiple-output (SIMO) wireless power transfer systems is examined. Closed-form solutions for the receiver loads that maximize either the total efficiency or the efficiency for a specific receiver are derived. They are validated with the solutions obtained using genetic algorithm (GA) optimization. The optimum load values required to maximize the total efficiency are found to be identical for all the receivers. Alternatively, the loads of receivers can be adjusted to deliver power selectively to a receiver of interest. The total efficiency is not significantly affected by this selective power distribution. A SIMO system is fabricated and tested; the measured efficiency matches closely with the efficiency obtained from the theory.

Key Words: Efficiency, Multiple-Input Multiple-Output System, Multiple Receivers, Optimum Loads, Wireless Power Transfer.

I. INTRODUCTION

Wireless power transfer (WPT) technology has been actively studied and developed over the past several years and is considered to be one of the most important and promising key techniques to find widespread application in the forthcoming IT industries. Many products related to single-input single-output (SISO) WPT systems, such as charging units for mobile phones and home appliances, are already available in commercial markets. Most of them are based on the inductive or resonant operating mode [1]; the latter is expected to gain more support from the market because it enables an extended power transfer range [2]. Various studies have been conducted focusing on higher efficiencies or longer transfer ranges. For example, WPT systems with a slab of metamaterial were studied for a stronger near-field coupling

between two resonant coils [3]. Recently, the multiple-input multiple-output (MIMO) WPT technology has drawn attention of researchers and industries, particularly with the growing interest in the energy autonomy of the Internet of Things (IoT) sensors [4–7]. Although general analyses about MIMO WPT systems are found in literature, their characteristics have been usually examined in detail for some special cases of SIMO or MISO systems [8–13]. From circuit modeling analysis, Bou-Balust et al. [8] claimed that in SIMO systems, the total system efficiency can significantly improve as the number of receivers increases. In another SIMO-related approach [9], the conventional four-coil structure was extended to accommodate a multiple-receiver system with an example of one sending coil, one receiving coil, and two load coils. In [10], the effects of transmit diversity were investigated both analytically and through simulations for

the power transfer with multiple transmitters (MISO). The power transfer efficiencies and distribution of magnetic fields were analyzed for a system of multiple misaligned transmitters and a single receiver. In [11–13], a method of providing adjustable power distribution for multiple receivers was presented with an upper bound of efficiency. This work, however, adopted a simplifying assumption that the optimum loads of the receivers are proportional to their internal loss resistances with a constant proportionality ratio.

In the present study, various features of SIMO systems are examined with closed-form optimum loads to maximize the total system efficiency. We demonstrate that the optimum loads are identical for all receivers without the assumption made in [11]. Our results are somewhat different from [8] in that the total efficiency of SIMO systems does not increase significantly as the number of receivers increases. The optimal loads obtained from the closed-form solution are validated with the genetic algorithm (GA) optimization results. Lastly, the theoretical efficiencies with the optimal loads used in this study are compared with electromagnetic simulation and measurement results; they show good agreement with each other.

This paper is organized as follows. In Section II, general MIMO WPT systems are formulated on the basis of circuit theory, and the important behaviors of a typical SISO system are summarized for the purpose of reference. In Section III, the cases of a SIMO system with one transmitter and multiple receivers are analyzed in detail in terms of efficiencies and coupling coefficient interpretations. The total efficiency of typical SIMO systems is shown not to change much as the number of receivers increases. This enables controlled power distribution among the receivers without changing the total efficiency considerably. In Section IV, some important findings of this work are summarized with conclusions.

II. MODELING OF MIMO WIRELESS POWER TRANSFER SYSTEM

Fig. 1 shows a typical MIMO WPT system, with M transmitters and N receivers. All the loops have some inductances and resistances. We assume that each loop is loaded with a capacitor to resonate at a specific design frequency. In addition, we assume that the M transmitters are excited by voltage sources and that N receivers have extra load resistances to receive transferred powers. Once the sizes and positions of the transmitters and receivers are specified, the coupling coefficients can be determined in a straightforward manner [14, 15]. Then, the WPT system can be analyzed in various aspects. The general MIMO WPT system is commonly analyzed using Z-matrix formulation [16, 17]. The Z matrix as a function frequency is given by

Fig. 1. A general configuration of a MIMO WPT system with M transmitters and N receivers.

$$\begin{bmatrix} V_1 \\ \vdots \\ V_M \\ 0 \\ \vdots \\ 0 \end{bmatrix} = \begin{bmatrix} Z_{11} & \cdots & Z_{1,M} & \cdots & Z_{1,M+N} \\ \vdots & & & & \vdots \\ Z_{M,1} & & & & Z_{M,M+N} \\ Z_{M+1,1} & & & & Z_{M+1,M+N} \\ \vdots & & & & \vdots \\ Z_{M+N,1} & \cdots & \cdots & Z_{M+N,M+N} \end{bmatrix} \begin{bmatrix} I_1 \\ \vdots \\ I_M \\ I_{M+1} \\ \vdots \\ I_{M+N} \end{bmatrix}. \quad (1)$$

In (1), the first M elements in the column matrix $[V]$ are the supplied voltages. The supplied voltages $V_n (= |V_n| \angle \theta_n, n = 1, 2, \dots, M)$ may be complex numbers in general. The principal diagonal elements of $[Z]$ are expressed as

$$Z_{n,n} = R_n + j\omega_0 L_n \left(\frac{\omega}{\omega_0} - \frac{\omega_0}{\omega} \right) \quad (2)$$

for $n = 1, 2, \dots, M$ and

$$Z_{n,n} = R_n + R_{L,n} + j\omega_0 L_n \left(\frac{\omega}{\omega_0} - \frac{\omega_0}{\omega} \right) \quad (3)$$

for $n = M+1, M+2, \dots, M+N$, where ω_0 is the common angular resonant frequency of each loop, R_n 's are the loop resistances, L_n 's are the loop self-inductances, $\omega_0 L_n$'s are the reactance slope parameters of the loop resonator, and $R_{L,n}$'s are the extra load resistances for the receivers. The other elements of $[Z]$ are given by

$$Z_{m,n} = -j\omega M_{m,n} = -j\omega k_{m,n} \sqrt{L_m L_n} \quad (m \neq n) \quad (4)$$

for $m, n = 1, 2, \dots, M, M+1, \dots, M+N$, where $M_{m,n}$ and $k_{m,n}$'s are the mutual inductances and coupling coefficients between two loops, respectively [18].

When all the elements of the Z-matrix are given, the current at each loop is determined by $[I] = [Z]^{-1}[V]$. Then, the total input power and the received power at each receiver are given by

$$P_{in} = \sum_{n=1}^M \frac{1}{2} \text{Re}[V_n I_n^*] \quad (5)$$

and

$$P_{Ln} = \frac{1}{2} R_{Ln} |I_n|^2 \quad (n = M+1, M+2, \dots, M+N). \quad (6)$$

The efficiency at the n^{th} receiver is defined as

$$\eta_n = \frac{P_{Ln}}{P_{in}} \quad (n = M+1, M+2, \dots, M+N) \quad (7)$$

and the total efficiency is the sum of (7) and given by

$$\eta_t = \sum_{n=M+1}^{M+N} \eta_n. \quad (8)$$

Once all the elements of the Z-matrix in (1), including V_n 's, R_n 's, and R_{Ln} 's for a MIMO system, are specified, the WPT efficiencies can be easily evaluated at a design frequency ω_0 using (5)–(8). Commonly, we aim to maximize (7) or (8). For this purpose, we may decide the values of R_{Ln} 's by either an analytical or some numerical optimization methods. In this study, we focus on SIMO WPT systems and obtain closed-form solutions for the optimal loads.

Before we analyze SIMO WPT systems in various configurations, we review a SISO system for reference. In a SISO system ($M=1, N=1$), the WPT efficiency η_2 is compactly expressed [19] as

$$\eta_2(F_{21}, b_2) = \frac{F_{21}^2}{\left(1 + b_2 \sqrt{1 + F_{21}^2}\right) \left(1 + \frac{1}{b_2} \sqrt{1 + F_{21}^2}\right)} \quad (9)$$

where $b_2 (= R_{L2}/R_{L2,opt})$ is the load deviation factor with respect to the optimum ($R_{L2,opt}$), which is [20]

$$R_{L2,opt} = R_2 \sqrt{1 + F_{21}^2}. \quad (10)$$

In (9) and (10), $F_{21} (= k_{21} Q_{21} = k_{21} \sqrt{Q_2 Q_1})$ is the figure of merit for the SISO system. Some notable features from (9) are as follows: when $b_2 = 1$ ($R_{L2} = R_{L2,opt}$) in (9), the system is at the optimum state and the efficiency touches the upper bound. When $b_2 > 1$ or $b_2 < 1$, the system is in the under-coupled or the over-coupled region, respectively, and the efficiencies are lower than the maximum. Explicitly, the efficiency degrades symmetrically with the deviation of b_2 from unity in a log scale. For example, with $b_2 = 10$ or $1/10$, the efficiency degrades in a same rate from (9). Likewise, whether when $b_2 \rightarrow \infty$ (open-circuited or under-coupled limit) or when $b_2 \rightarrow 0$ (short-circuited or over-coupled limit), $\eta_2 \rightarrow 0$. Lastly, when $F_{21} \rightarrow \infty$ or 0 , $\eta_2 \rightarrow 1$ or 0 irrespective of b_2 as long as b_2 has a finite value.

III. VARIOUS CONFIGURATIONS IN SIMO SYSTEM

1. SIMO System with $M=1$ and $N=2$

Fig. 2. A SIMO system with $M=1$ and $N=2$.

Consider the case of a SIMO system with $M=1$ and $N=2$ shown in Fig. 2. One Tx loop and two Rx loops may be randomly positioned according to the required system configuration. If the coupling coefficients between the two receiving loops (k_{23}) are negligibly small compared with k_{21} and k_{31} , we may assume $k_{23} = 0$ and can express the efficiencies for Rx 2 (η_2) and for Rx 3 (η_3) as

$$\eta_2(\beta_2, \beta_3) = \frac{\beta_2}{(1 + \beta_2)} \cdot \frac{F_{21}^2}{\left[1 + \beta_2 + F_{21}^2 + \frac{(1 + \beta_2)}{(1 + \beta_3)} F_{31}^2\right]} \quad (11)$$

and

$$\eta_3(\beta_2, \beta_3) = \frac{\beta_3}{(1 + \beta_3)} \cdot \frac{F_{31}^2}{\left[1 + \beta_3 + F_{31}^2 + \frac{(1 + \beta_3)}{(1 + \beta_2)} F_{21}^2\right]} \quad (12)$$

as functions of β_2 and β_3 , which are the normalized load resistances defined by R_{L2}/R_2 and R_{L3}/R_3 , respectively. F_{21} and F_{31} are the figures of merit given by $k_{21} \sqrt{Q_2 Q_1}$ and $k_{31} \sqrt{Q_3 Q_1}$, respectively. The approximations (11) and (12) are relatively accurate as long as $F_{23} \leq \frac{F_{21}}{2}$ or $\frac{F_{31}}{2}$. Observing η_2 in (11), we see that as $\beta_3 \rightarrow \infty$ (open-circuited) or $F_{31} \rightarrow 0$ (Rx 3 placed far away from Tx 1, for example), the role of Rx 3 vanishes and (11) can be shown to reduce to (9) [19, 20]. The total efficiency η_t is the sum of (11) and (12), and is given by

$$\eta_t(\beta_2, \beta_3) = \eta_2 + \eta_3. \quad (13)$$

To find the optimum normalized load $\beta_{2,opt}$ with which η_2 is maximized for a fixed β_3 , we require

$$\frac{\partial \eta_2(\beta_2, \beta_3)}{\partial \beta_2} = 0 \quad (14)$$

which is solved to give

$$\beta_{2,opt} = \frac{R_{L2,opt}}{R_2} = \sqrt{\frac{1 + F_{21}^2 + \frac{F_{31}^2}{1 + \beta_3}}{1 + \frac{F_{31}^2}{1 + \beta_3}}} \quad (15)$$

In (15), we can see that the normalized optimum load $\beta_{2,opt}$ depends on β_3 . Especially when $\beta_3 \rightarrow \infty$ (open-circuited) or $F_{31} \rightarrow 0$ (Rx 3 placed far way), the system practically behaves like a SISO and $\beta_{2,opt}$ becomes $\sqrt{1 + F_{21}^2}$ to be consistent with (10). Similarly, the optimum load to maximize η_3 for a fixed β_2 is

$$\beta_{3,opt} = \frac{R_{L3,opt}}{R_3} = \sqrt{\frac{1 + F_{31}^2 + \frac{F_{21}^2}{1 + \beta_2}}{1 + \frac{F_{21}^2}{1 + \beta_2}}} \quad (16)$$

On the other hand, to find the optimum loads with which the total efficiency η_t (13) is maximized, the following two equations should be satisfied simultaneously:

$$\frac{\partial \eta_t(\beta_2, \beta_3)}{\partial \beta_2} = 0 \quad (17)$$

and

$$\frac{\partial \eta_t(\beta_2, \beta_3)}{\partial \beta_3} = 0 \quad (18)$$

The solution of (17) and (18) can be shown to be

$$\beta_{2,opt} = \beta_{3,opt} = \sqrt{1 + F_{12}^2 + F_{13}^2} \quad (19)$$

It turns out that $\beta_{2,opt}$ is equal to $\beta_{3,opt}$. For some illustrations with respect to the SIMO system in Fig. 2, we assume that $r_1 = 15$ cm, $r_2 = r_3 = 5$ cm (which is chosen to represent the size of typical mobile phones), the radius of each loop ring (r_{ring}) is 0.2 cm, and the resonant frequency (f_0) is 6.78 MHz.

In Fig. 3, we plot the efficiencies as a function of β_2 and β_3 using (11), (12), and (13). The center positions of one Tx and two Rx loops are (0, 0, 0), (0, -15, 10), and (0, 7.5, 25), respectively. The Q-factors of Tx 1, Rx 2, and Rx 3 are 730, 630, and 630, respectively. For this example, $F_{21} = 11$ and $F_{31} = 5.8$. Fig. 3(a) and (b) show that when β_2 is about 4 and $\beta_3 \rightarrow \infty$, η_2 is maximized to 0.82. Meanwhile, when $\beta_2 \rightarrow \infty$ and β_3 is approximately 2, η_3 is maximized to 0.52. The maximum total efficiency η_t in Fig. 3(c) is about 0.85 when β_2 and β_3 are about 12, as expected by (19). Note that while the efficiencies η_2 and η_3 significantly vary depending on β_2 and β_3 , the total efficiency η_t is rarely sensitive as long as they are greater than approximately 4. This is an interesting property of SIMO systems since the efficiency for each receiver may be properly distributed considering the charged battery energy levels of the receivers while the total remains unchanged.

Fig. 3. Efficiencies as a function of the normalized load resistances β_2 and β_3 in a SIMO system: (a) η_2 , (b) η_3 , and (c) η_t . $M=1$, $N=2$, $r_1=15$ cm, $r_2=r_3=5$ cm, $r_{ring}=0.2$ cm, $F_{21}=11$, $F_{31}=5.8$, the centers of Tx and Rx loops are (0, 0, 0), (0, -15 cm, 10 cm), and (0, 7.5 cm, 25 cm), respectively.

Fig. 4. Efficiencies for different positions (0, 10, v) of Rx 3 and fixed positions of Tx 1 and Rx 2 at (0, 0, 0) and at (0, -10 cm, 15 cm), respectively ($r_1=15$ cm, $r_2=r_3=5$ cm, $r_{ring}=0.2$ cm and $R_2=R_3=0.017 \Omega$).

Fig. 4 shows η_2 , η_3 , and η_t for different center positions (0, 10, v) of loop 3 (Rx 3) in Fig. 2. For this example, the centers of loop 1 (Tx 1) and loop 2 (Rx 2) are fixed at (0, 0, 0), (0, -10, 15), respectively. At each position of Rx 3, $\beta_{2,opt}$ and $\beta_{3,opt}$ given by (19) are shown in Fig. 4. Alternatively, β_2 and β_3 can be optimized to maximize the fitness function η_t (8) using the GA in MATLAB based on (1)–(7). The optimized β_2 and β_3 are in good agreement with $\beta_{2,opt}$ and $\beta_{3,opt}$ obtained by (19). This demonstrates the validity of (19). In the GA optimization of this study, all the coupling effects are considered.

2. SIMO System with one Tx and N Rx's (Same Receiving Loops Are Symmetrically Positioned)

Now, we consider a more general case of the SIMO system, where all the N Rx loops are identical and symmetrically located around one Tx loop. From the symmetry of the system, the figure of merit ($F=kQ$) between the Tx and Rx loops should also be identical. When the coupling coefficients between the Rx loops are negligibly small, the total efficiency η_t and the efficiency for each loop η can be expressed as

$$\eta_t = N\eta(b, F) = \frac{NF^2}{\left(1 + b\sqrt{1 + NF^2}\right)\left(1 + \frac{1}{b}\sqrt{1 + NF^2}\right)} \quad (20)$$

where $b (=R_L/R_{L,opt})$ is the load deviation factor from the optimum load resistance, given as

$$R_{L,opt} = R\sqrt{1 + NF^2}. \quad (21)$$

The expressions (20) and (21) are the extensions of (9) and (10) for the SISO system. When $N=1$, (20) and (21) reduces to (9) and (10), respectively.

Table 1 shows the optimum load resistances ($R_{L,opt}$) for different number of receivers. Again, the solutions from GA optimization are consistent with the closed-form solution in (21), validating the formulations. As the separation between the Tx and Rx loops increases, the figure of merit (F) and the optimum load $R_{L,opt}$ usually become very small, as exemplified in Table 1. Ideally, these small optimum resistances can be transformed to the 50 Ω impedance of typical receivers using a feeding loop. In practice, we may use a multi-turn Rx loop to increase the optimum resistance enough to make it directly match practical receivers [21].

Fig. 5(a) shows a SIMO system ($M=1, N=4$) with four symmetrically placed receivers. The Tx loop is centered at the origin. The vertical and horizontal distances of each Rx loop from the origin are v and h , respectively. Fig. 5(b) shows the fabricated SIMO system based on Fig. 5(a). Additional feeding loops for the Rx loops were used for 50- Ω matching to measure the S -parameters using a network analyzer. Table 2 shows the approximated [21, 22] and measured values of circuit elements. The measured values were obtained using the Keysight E5063A VNA. The measured resistances were about two times the theoretical ones. This has been a usual phenomenon due to oxidiza-

Fig. 5. SIMO system ($M=1, N=4$) with symmetrically placed receivers. (a) SIMO geometry and (b) photograph of fabricated SIMO structure.

tion of copper wires [23]. On the other hand, the inductances and capacitances are in close agreement. The measured Q of the transmitting loop and receiving loops are approximately 330 and 234, respectively.

Fig. 6 shows the efficiencies for different numbers (N) of Rx loops in the SIMO system. The resonant frequency (f_0) is 6.78 MHz, $r_1=15$ cm, $r_2=r_3=r_4=r_5=5$ cm, the radius of each loop (r_{ring}) is 0.2 cm, $v=7.5$ cm, and $h=15$ cm in connection

Fig. 6. WPT efficiencies depending on the number of Rx loops (N) in the SIMO system ($r_1=15$ cm, $r_2=r_3=r_4=r_5=5$ cm, $r_{ring}=0.2$ cm, $v=7.5$ cm, $h=15$ cm, $k_{21}=k_{31}=k_{41}=k_{51}=0.02072$).

Table 1. Optimum load resistances ($R_{L,opt}$)

Number of Rx loops	GA optimization (Ω)	Closed-form (21) (Ω)
1	0.202	0.202
2	0.282	0.282
3	0.346	0.344
4	0.409	0.397

The receivers are symmetrically placed $h=15$ cm and $v=7.5$ cm.

with Fig. 5.

The solid lines are obtained from the GA optimization using the measured circuit values summarized in Table 2. The dashed lines show the efficiencies from the closed-form expression (20). The square symbols show the measured efficiencies using a two-port network analyzer (Fig. 5). It is shown that as the number of Rx loops (N) increases, the total efficiency (η_t) increases to some extent. The efficiency (η_n) for each Rx loop is roughly the total efficiency (η_t) divided by the number of Rx loops N . The efficiencies obtained by the numerical calculations using the GA method, closed-form expressions, and measurements are all in good agreement. In Table 3, we summarize the coupling coefficients between the Tx and Rx loops and between two adjacent Rx loops for different numbers (N) of receivers from 1 to 4 with the configurations described in Figs. 5 and 6. As we have first assumed, the coupling coefficients between the Tx and Rx loops are considerably larger than those between the two adjacent Rx loops. This explains why the efficiencies obtained from the closed-form expressions (20) and (21), neglecting the coupling coefficients between the two adjacent Rx loops, agree well with those obtained from the numerical optimization and measurements.

3. SIMO System with $M=1$ and $N=4$ (Same Receiving Loops, But Not Symmetrically Positioned)

To analyze the effects of placing the Rx loops over the transmitter with different densities, we have evaluated the efficiencies for three configurations (cases A, B, and C) as shown in Fig. 7. The angles of the two Rx loops seen from the origin are 90° , 60° , and 41° for cases A, B, and C, respectively. For all the three cases, $r_1 = 15$ cm, $r_2 = r_3 = r_4 = r_5 = 5$ cm, the radius of the loop

Fig. 7. Three special cases of SIMO system ($M=1$, $N=4$) with unsymmetrically placed receivers ($r_1=15$ cm, $r_2=r_3=r_4=r_5=5$ cm, $r_{ring}=0.2$ cm, $h=15$ cm, and v is the vertical distance between Tx1 and each Rx loop).

ring is 0.2 cm, $h=15$ cm, and the Rx loops are placed right above the Tx loop with a vertical distance of v .

In Fig. 8(a), we show the total efficiencies η_t obtained using GA as the vertical distance v increases. The system has been optimized to maximize η_t 's for each case. The total efficiency for case A is shown to decrease approximately from 88% to 50% as v increases from 2 cm to 24 cm. The total efficiency for case C is 3%–10% lower than that for case A due to the effect of the stronger mutual couplings between the Rx loops. In Fig. 8(b), η_2 ($=\eta_5$) for case C is shown to be the highest, and η_3 ($=\eta_4$) for case C is shown to be the lowest and to approach zero when v is about 25 cm. The differences of η_2 and η_3 increase as v increases for case B. This is due to the effects of the mutual coupling between the Rx loops becoming relatively stronger as v increases.

In Fig. 9, the optimum load resistances ($R_{L,opt}$) are obtained from GA and plotted as a function of v for the three cases. The optimum load resistances $R_{L2,opt}$ ($=R_{L5,opt}$) for all of the three cases are shown to decrease as expected when v increases. On the other hand, $R_{L3,opt}$ ($=R_{L4,opt}$) for case C shows a tendency to increase due to the effect of the strongest mutual coupling between Rx loops.

In Table 4, we show the coupling coefficients for cases A, B, and C. The minus sign implies that the magnetic flux lines generated from one Rx loop cross the other Rx loop in an opposite direction and may counter the flux lines coming from the Tx loop. The coupling coefficients between the Rx loops do not change depending on v . However, as v increases from 1 cm to 25 cm, the coupling coefficient between the Tx loop and any of the Rx loops ($k_{21}=k_{31}=k_{41}=k_{51}$) decreases from 0.0357 to 0.006. The absolute value of k_{32} for case C is the largest ($=0.0654$), which is even larger than k_{n1} ($=0.0357$) for $n=2-5$. Therefore, the efficiency η_3 ($=\eta_4$) for case C is the lowest.

Table 2. Approximated and measured circuit values

Circuit elements	Approximated [21, 22]	Measured
R_1 (Ω)	0.051	0.11
R_2-R_5 (Ω)	0.017	0.04

$r_1=15$ cm, $r_2=r_3=r_4=r_5=5$ cm, $r_{ring}=0.2$ cm, $h=15$ cm.

Fig. 10. SIMO system ($M=1$, $N=4$) where one Rx loop (Rx 5) moves outward from the center ($r_1=15$ cm, $r_2=r_3=r_4=r_5=5$ cm, $r_{ring}=0.2$ cm, v is the vertical distance between Tx1 and each Rx loop).

For this case, $r_1=15$ cm, $r_2=r_3=r_4=r_5=5$ cm, and the radius of the Rx loop ring is 0.2 cm. In Fig. 11(a) and (b), the efficiencies and the optimum load resistances obtained using GA are shown as a function of h_5 . The optimum load resistances have been obtained using the GA to maximize the total efficiencies (η_t) for each h_5 with all mutual couplings considered. In Fig. 11(a), we can see that η_t 's do not change much as h_5 increases from 0 to 26 cm. It only decreases from 87% to 80%. However, the efficiency of each receiver does change significantly. Obviously, η_5 decreases most dramatically from 64% to a few percent. Instead, η_2 ($=\eta_4$) and η_3 are shown to increase from about 10% to 26%. One important observation is that the total efficiency can be maintained rather steady while the efficiency for each receiver changes considerably.

IV. CONCLUSION

Various features of WPT SIMO systems have been investigated on the basis of a more general MIMO system formulation. Useful closed-form expressions for the efficiencies and optimum loads for SIMO systems have been derived and their validity was checked through GA optimization and measurement. The results of this study have provided physical insight that can be employed to any practical SIMO WPT systems and have demonstrated the feasibility of SIMO systems in the range of tens of centimeters with sufficient design examples.

Fig. 11. Efficiencies and optimum load resistances obtained using GA for the SIMO system in Fig. 10 ($M=1$, $N=4$). (a) Efficiencies by h_{rx5} and (b) optimum load resistances by h_{rx5} . $r_1 = 15$ cm, $r_2 = r_3 = r_4 = r_5 = 5$ cm, $r_{ring} = 0.2$ cm, $v = 7.5$ cm.

This research was supported by the Ministry of Science, ICT and Future Planning, Korea, under the Information Technology Research Center support program (No. IITP-2018-2016-0-00291) supervised by the IITP (National IT Industry Promotion Agency).

Sejin Kim

received the B.S. degree in Electronics and Radio Engineering from Kyung Hee University, Yongin, Korea, in 2015. She is currently pursuing a master's degree in Electronics and Radio Engineering from Kyung Hee University. Her fields of research include wireless power transfer systems, passive devices, small antennas, RFID reader antennas, and metamaterials.

Sanghoek Kim

received the B.S. degree with a double major in Electrical Engineering and Mathematics from Seoul National University, Seoul, Korea, in 2007, and the M.S. and Ph.D. degrees in electrical engineering from Stanford University, CA, USA, in 2013. His research focuses on applications of radio-frequency technology and electromagnetics theory in wireless power transfer, communications, and signal integrity in high-speed channels. After graduation, he has worked at Qualcomm Inc. as a signal/power integrity engineer and in SiBeam Inc., as a millimeter-wave system engineer. Currently, he is an assistant professor in the Department of Electronics and Radio Engineering in Kyung Hee University.

Sungyoun Hwang

received the B.S. degree in Information and Communication Engineering from Soonchunhyang University, Asan, Korea, in 2015. He is currently pursuing a master's degree in Electronics and Radio Engineering from Kyung Hee University. His fields of research include wireless power transfer systems, passive devices, and small antennas.

Bomson Lee

received the B.S. degree in Electrical Engineering from Seoul National University, Seoul, Korea, in 1982. From 1982 to 1988, he was with the Hyundai Engineering Company Ltd., Seoul, Korea. He received the M.S. and Ph.D. degrees in Electrical Engineering from the University of Nebraska, Lincoln, NE, USA, in 1991 and 1995, respectively. In 1995, he joined the faculty at Kyung Hee University, where he is currently a professor in the Department of Electronics and Radio Engineering. From 2007 to 2008, he was the chair of the technical group for microwave and radiowave propagation in KIEES (Korea Institute of Electromagnetic Engineering & Science). In 2010, he was an Editor-in-Chief of the *Journal of the Korean Institute of Electromagnetic Engineering and Science*. Since 2015, he has been a vice-chairman in KIEES. His research activities include microwave antennas, RFID tags, microwave passive devices, wireless power transfer, and metamaterials.
